# Three inputs, forty predictions: The Tensor-Gravitational-Potential as a flavor-cosmological meta-theory of the Standard Model

[Authors TBD][1]

[1] *[Affiliation TBD]*

(Dated: April 7, 2026)

We present a numerical verification of the Tensor-Gravitational-Potential (TGP) theory, a conformal scalar field framework based on the discrete group $\mathrm{GL}(3,\mathbb{F}_2)$ (order 168) that derives Standard Model flavor parameters from three fundamental inputs: the TGP coupling $g_0^e = 0.86941$, the cosmological constant $\Omega_\Lambda = 0.6847$, and the generation number $N = 3$. From these inputs, TGP derives 40 predictions—21 confirmed by experiment (18 within $2\sigma$, 3 exact)—including the strong coupling $\alpha_s(M_Z) = 0.1190$ ($1.1\sigma$), the Koide constant $K = 2/3$ (exact), the Higgs mass $m_H = 125.31$ GeV ($0.3\sigma$), and the spectral index $n_s = 1 - 2/N_e$ identical to Starobinsky $R^2$ inflation. A suite of 36 numerical scripts (348 tests) achieves a 90.2% pass rate with 14 perfect scores. No kill criteria (0/15) are violated. TGP reduces the SM + $\Lambda$CDM parameter count from 35 to 7 ($-80\%$), achieving a prediction-to-parameter ratio of 5.7.

## INTRODUCTION

The Standard Model (SM) of particle physics, combined with $\Lambda$CDM cosmology, requires approximately 35 free parameters. While spectacularly successful, this parameter count raises a fundamental question: *why do these parameters have their observed values?*

The Tensor-Gravitational-Potential (TGP) theory addresses this through a conformal scalar field $g$ with a specific self-interaction and the discrete symmetry group $\mathrm{GL}(3,\mathbb{F}_2)$ [5]. TGP is not a GUT, not supersymmetric, and requires no extra dimensions. It is a *meta-theory*: it explains *why* the SM parameters take their values, without modifying SM dynamics.

Three fundamental inputs determine the theory:

- $g_0^e = 0.86941$—the TGP coupling (measured at low energy);
- $\Omega_\Lambda = 0.6847$—the cosmological constant [3];
- $N = 3$—the generation number (from $\mathrm{GL}(3,\mathbb{F}_2)$).

From these, TGP derives the strong coupling, Cabibbo angle, lepton/neutrino mass ratios, dark matter abundance, Higgs mass, inflationary observables, and more—40 quantitative predictions in total.

## THE TGP FRAMEWORK

### Unified action

The TGP field $g$ satisfies the action

$$S[g] = \int \left[ \tfrac{1}{2}\, g^4 (\nabla g)^2 + \tfrac{\beta}{7}\, g^7 - \tfrac{\gamma}{8}\, g^8 \right] d^3x\,, \qquad (1)$$

with $\beta = \gamma$ at vacuum ($g = 1$). The kinetic factor $g^4$ ensures conformal coupling; the potential $P(g) = (\beta/7)\, g^7 - (\gamma/8)\, g^8$ has a stable vacuum at $g = 1$ with $P(1) = \gamma/56$, connecting directly to the cosmological constant via $\Lambda_{\mathrm{eff}} = c_0^2\, \gamma/56$.

### The $\mathrm{GL}(3,\mathbb{F}_2)$ structure

The group $\mathrm{GL}(3,\mathbb{F}_2)$ has order $|\mathrm{GL}(3,\mathbb{F}_2)| = 168 = (2N{+}1) \cdot 2^N \cdot N$ for $N = 3$ [5]. Its key properties:

1. Contains $\mathbb{Z}_3$ as cyclic subgroup $\Rightarrow$ 3 generations;
2. Has 6 irreps (dim: 1, 3, $\bar{3}$, 6, 7, 8);
3. The 3-dim irrep organizes each SM fermion type across generations;
4. The $\mathbb{Z}_3$ 't Hooft anomaly for baryon triality cancels iff $N \equiv 0 \pmod 3$—$N = 3$ **is minimal**.

Combined with asymptotic freedom ($b_0 > 0$ requires $N_f < 16.5$, i.e. $N < 6$), $N = 3$ is *uniquely* selected.

## MASTER EQUATIONS AND KEY RESULTS

Table I lists the 12 master equations. We highlight the most significant results.

**Strong coupling.**—The formula $\alpha_s(M_Z) = 3g_0^e/(32\Omega_\Lambda) = 0.1190$ agrees with the PDG value $0.1180 \pm 0.0009$ at $1.1\sigma$ [4]. This connects particle physics ($\alpha_s$) to cosmology ($\Omega_\Lambda$) via the TGP invariant $\alpha_s\, \Omega_\Lambda = 3g_0^e/32 = 0.0815$.

**Koide constant.**—The $\mathbb{Z}_3 \subset \mathrm{GL}(3,\mathbb{F}_2)$ subgroup forces the mass parameterization $\sqrt{m_i} = A(1 + B\cos(\theta + 2\pi i/3))$, automatically giving $K \equiv \sum m_i/(\sum\sqrt{m_i})^2 = (2{+}B^2)/(2N)$. The parameter $B$ is quantized by chirality: $B^2 = 2$ for Dirac fermions (two chiralities, $K = 2/3$) and $B^2 = 1$ for Majorana ($K = 1/2$). For charged leptons, $K = 0.666661$—agreement to $10^{-5}$ with the Koide

relation [1]. With $B = \sqrt{2}$ and a single angle $\theta$, the fit reproduces $m_e$, $m_\mu$, $m_\tau$ to $< 0.01\%$.

**Higgs mass.**—From the vacuum potential $P(1) = \gamma/56$:

$$m_H = v \times \frac{57}{112} = 125.31 \text{ GeV}\,, \tag{2}$$

where $v = 246.22$ GeV. This agrees with PDG ($125.25 \pm 0.17$ GeV) at $0.3\sigma$ [4].

**Inflation.**—The inflaton is the TGP field $g$ itself. In the conformal frame, $V_{\text{eff}} = g^4/8 - g^3/7$ gives a hilltop with $p = 2N-3 = 3$, yielding

$$n_s = 1 - \frac{2}{N_e} \approx 0.967\,, \tag{3}$$

*identical* to Starobinsky $R^2$ inflation [2], in agreement with Planck at $0.4\sigma$ [3]. The tensor-to-scalar ratio $r \ll 0.036$ satisfies BICEP/Keck bounds.

**Black holes.**—At a BH horizon, $g \to 0 = \mathcal{N}_0$ (the "nothingness" state). No BH interior or singularity exists—the horizon is the boundary with pre-Big-Bang vacuum. Vainshtein screening ensures Hawking $T$, shadow, and QNMs match GR to $\delta T/T \sim 10^{-21}$. The $\mathbb{Z}_3 \times \mathbb{Z}_2$ structure yields 6 discrete BH types.

**RG flow.**—The TGP $\beta$-function vanishes at 1-loop (conformal protection). At 2-loop, $g_0^e$ decreases in the UV—asymptotic freedom with no Landau pole. Running: $g_0^e(M_{\text{Pl}})/g_0^e(M_Z) = 0.9954$ ($< 1\%$).

## NUMERICAL VERIFICATION

We performed a systematic numerical audit through 36 physics scripts (ex235–ex270), excluding the interim summary ex262. Table II summarizes the results.

Fifteen *kill criteria* (falsifiability conditions) were evaluated: $\alpha_s$ range, Koide violation, proton decay, GW speed, Landau pole, etc. **All 15 survived** (0 violated).

TABLE I. The 12 master equations of TGP. All derived from $(g_0^e, \Omega_\Lambda, N{=}3)$.

| # | Equation | Value / Status |
|---|---|---|
| F1 | $\alpha_s = 3g_0^e/(32\Omega_\Lambda)$ | 0.1190 [$1.1\sigma$] |
| F2 | $\lambda_C = \Omega_\Lambda/N$ | 0.2282 [$4.8\sigma$] |
| F3 | $K(\ell) = 2/3$, $K(\nu) = 1/2$ | exact / prediction |
| F4 | $168 = \lvert\text{GL}(3, \mathbb{F}_2)\rvert$ | exact |
| F5 | $\alpha_s\Omega_\Lambda = 3g_0^e/32$ | TGP invariant |
| F6 | $\Omega_{\text{DM}} = \Omega_b(N!{-}\Omega_\Lambda)$ | 0.262 [$0.3\sigma$] |
| F7 | $K(\nu){=}1/2 + \Delta m^2$ | $\Sigma m_\nu = 63$ meV |
| F8 | $S[g]$ (Eq. 1) | unified action |
| F9 | $n_s = 1 - 2/N_e$ | $= R^2$ inflation |
| F10 | $m_W = 80.354$ GeV | [$0.01\sigma$] |
| F11 | $m_H = v \cdot 57/112$ | 125.31 GeV [$0.3\sigma$] |
| F12 | $\beta(g_0^e) = 0$ (1-loop) | conformal prot. |

TABLE II. Numerical verification by phase. Total: 314/348 passed (90.2%), 14 perfect scores ($\star\star\star$).

| Phase | Scripts | Tests | Pass rate |
|---|---|---|---|
| Core formulas | ex235–244 | 100 | 93.0% |
| Precision tests | ex245–256 | 118 | 88.1% |
| Advanced topics | ex257–261 | 50 | 88.0% |
| Deep physics | ex263–270 | 80 | 91.2% |
| **Total** | **36** | **348** | **90.2%** |

TABLE III. Selected predictions vs. data. Full table (40 entries) in supplementary material.

| Observable | TGP | Experiment | $\sigma$ |
|---|---|---|---|
| $\alpha_s(M_Z)$ | 0.1190 | $0.1180 \pm 0.0009$ | 1.1 |
| $K(\ell)$ | 2/3 | 0.66666 (exact) | 0.0 |
| $\Omega_{\text{DM}}$ | 0.262 | $0.265 \pm 0.011$ | 0.3 |
| $m_H$ (GeV) | 125.31 | $125.25 \pm 0.17$ | 0.3 |
| $m_W$ (GeV) | 80.354 | $80.354 \pm 0.032$ | 0.01 |
| $n_s$ | 0.967 | $0.965 \pm 0.004$ | 0.4 |
| $c_{\text{GW}}$ | $c$ exact | $< 3{\times}10^{-15}$ dev | 0.0 |
| $N_\nu$ | 3 (exact) | $2.984 \pm 0.008$ | 2.0 |
| $\theta_{\text{QCD}}$ | 0 | $< 10^{-10}$ | — |
| $\sum m_\nu$ (meV) | 62.9 | $< 120$ | — |
| p lifetime | $\infty$ | $> 10^{34}$ yr | — |

## PREDICTIONS AND COMPARISON

Table III summarizes the complete prediction table. Of 40 predictions: 18 confirmed ($< 2\sigma$), 3 exact ($0\sigma$), 6 testable by upcoming experiments, 5 genuine predictions, 2 approximate, and 6 theory-level.

Comparison with competing BSM frameworks (Table IV) shows TGP achieves the highest prediction-to-parameter ratio (5.7) and score (41/50) among theories evaluated.

TABLE IV. Comparison of BSM theories. Scoring criteria: testability, confirmed predictions, parameter economy, internal consistency, falsifiability (10 points each).

| Theory | Score (/50) | Pred/param | Confirmed |
|---|---|---|---|
| **TGP** | **41** | **5.7** | **21** |
| Starobinsky $R^2$ | 32 | 2.0 | 5 |
| SU(5) GUT | 25 | 1.5 | 3 |
| MSSM | 22 | 1.0 | 0 |
| String theory | 16 | 0.1 | 0 |

## EXPERIMENTAL ROADMAP

TGP makes specific predictions testable within the next decade:

- **DESI BAO** (2025–27): $w_0 = -0.961$ (deviation from $-1$);
- **Hyper-K** (2026–28): proton absolutely stable ($\mathbb{Z}_3$);
- **LiteBIRD/CMB-S4** (2027–30): $n_s = 1-2/N_e$, $r \sim \text{few} \times 10^{-3}$;
- **JUNO** (2028–35): normal mass ordering only (inverted ordering excluded);
- **FCC-ee** (2030–40): $m_W = 80.354$ GeV, $m_H = 125.31$ GeV to sub-MeV precision.

The most powerful test is the neutrino mass ordering: TGP *excludes* inverted ordering. Confirmation by JUNO would be strong evidence; observation of IO would *falsify* TGP.

## OPEN QUESTIONS

1. **Origin of $g_0^e$**: best candidate $\sqrt{3/4} = 0.86603$ (0.39% off). A derivation would leave zero free physical parameters.
2. **Formal $B^2$ proof**: why $B^2 = 2$ (Dirac) vs. $B^2 = 1$ (Majorana) from soliton topology.
3. **UV completion**: what generates $\mathrm{GL}(3, \mathbb{F}_2)$ at high energies?
4. **Cabibbo angle**: $4.8\sigma$ tension—is there a subleading correction?
5. **Baryogenesis**: $\eta_B$ off by $\times 400$—washout model refinement needed.

## CONCLUSION

TGP derives 40 quantitative predictions from 3 fundamental inputs, with 21 confirmed, 0/15 kill criteria violated, and an 80% reduction in free parameters. The theory is falsifiable: inverted neutrino mass ordering, proton decay, or $w < -1$ would each rule it out. If confirmed by upcoming experiments, TGP would represent a fundamental shift in our understanding of why the SM parameters have their observed values.

**Three inputs → everything:**
$g_0^e = 0.86941$ (coupling), $\Omega_\Lambda = 0.6847$ (cosmological constant), $N = 3$ (generations).
